

9.3 Genetic Diversity

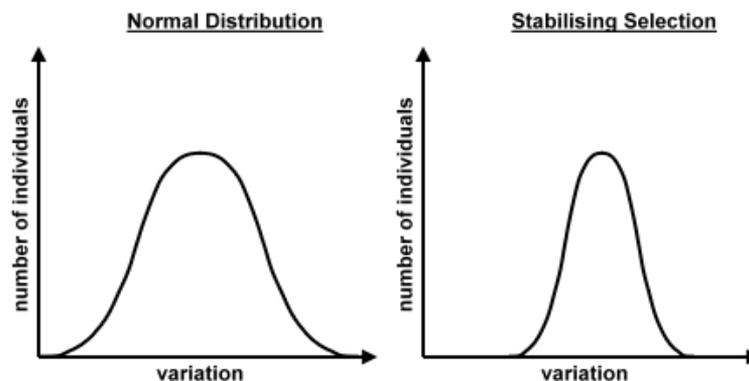

Genetic Diversity: Total number of different alleles in a population

Natural selection: (pg 230)

1. Any population has a gene pool with a wide variety of alleles
2. Random mutation leads to new alleles with the population
3. If a selection pressure is applied (i.e. change in climate, use of antibiotics), some alleles may confer a selective advantage
4. Organisms with these alleles are more likely to survive and reproduce
5. These new alleles get passed on to the next generation
6. Over time the frequency of advantageous alleles will increase in the population

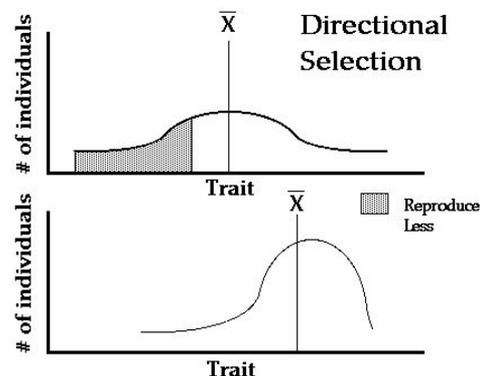

Natural selection: Stabilising selection (pg 233)

1. Environment remains stable
2. Individuals with phenotypes close to the mean are selected, more likely to pass on alleles
3. Those at the extremes are less likely to pass on their alleles
4. The median remains unchanged

Natural selection: Directional selection (pg 231)

1. Environment changes, selection pressure applied
2. Alleles at one extreme selected for, and the alleles at the other end selected against
3. The median changes

10.4 Investigating diversity (pg 249): will be covered in class

10.5 **Quantitative investigations** (pg 253) - the maths has already been covered, I will just highlight the key points here.

Making measurement - the significance of random sampling

Random sampling involves taking measurements of individuals, selected from a population, **without bias**. All individuals have an equal chance of being selected. This ensures that the sample is **representative** of the population.

For example, if we are measuring the number of daisies in a field, we can minimise the effects of bias by the method outlined below:

- mark an area to be sampled using tape or twine
- divide the study area into grids
- use a random number generator to generate (paired) coordinates
- take samples at the intersection of coordinates

We can minimise the effects of chance by:

- using a large sample size - this increases reliability of the data
- using the correct statistical analysis to analyse the data - take a mean, and calculate standard deviation and/or standard error
